Men's Birth Expectations

Colette A. Allred & Karen B. Guzzo

Having children remains a central part of American men and women's lives, yet most research on childbearing behaviors and expectations focuses on women. In this profile, we use data from the 2011-2015 cycles of the National Survey of Family Growth to examine birth expectations among men aged 15-44. We examine the proportion who report expecting any births in the future, the total number of expected births (combining current number of children with number of expected births), and the expected timing of the next (or first) birth by key demographic factors. In this sample of men, 62% had no children, 15% one child, 13% two children, and 10% had three or more children.

Birth Expectations by Number of Current Children

Overall, almost 60% of men aged 15-44 expected to have a child in the future, but this varied widely by the number of children they had.

- Four out of five childless men expected to have a child in the future—only one in five men who did not have biological children did not intend to have any children.
- Half of men with one child wished to have another child in the future.
- Only 23% of men with two children and 14% of men with three or more children expected to have more children.

Total Number of Expected Children

Figure 2. Total Number of Expected Children Among Men Aged 15-44, by Current Number of Biological Children, 2013

Source: NCHS, NSFG, 2011-2015

Overall, men expected to have an average of 2.2 total children (combining current number of children and the number of expected children).

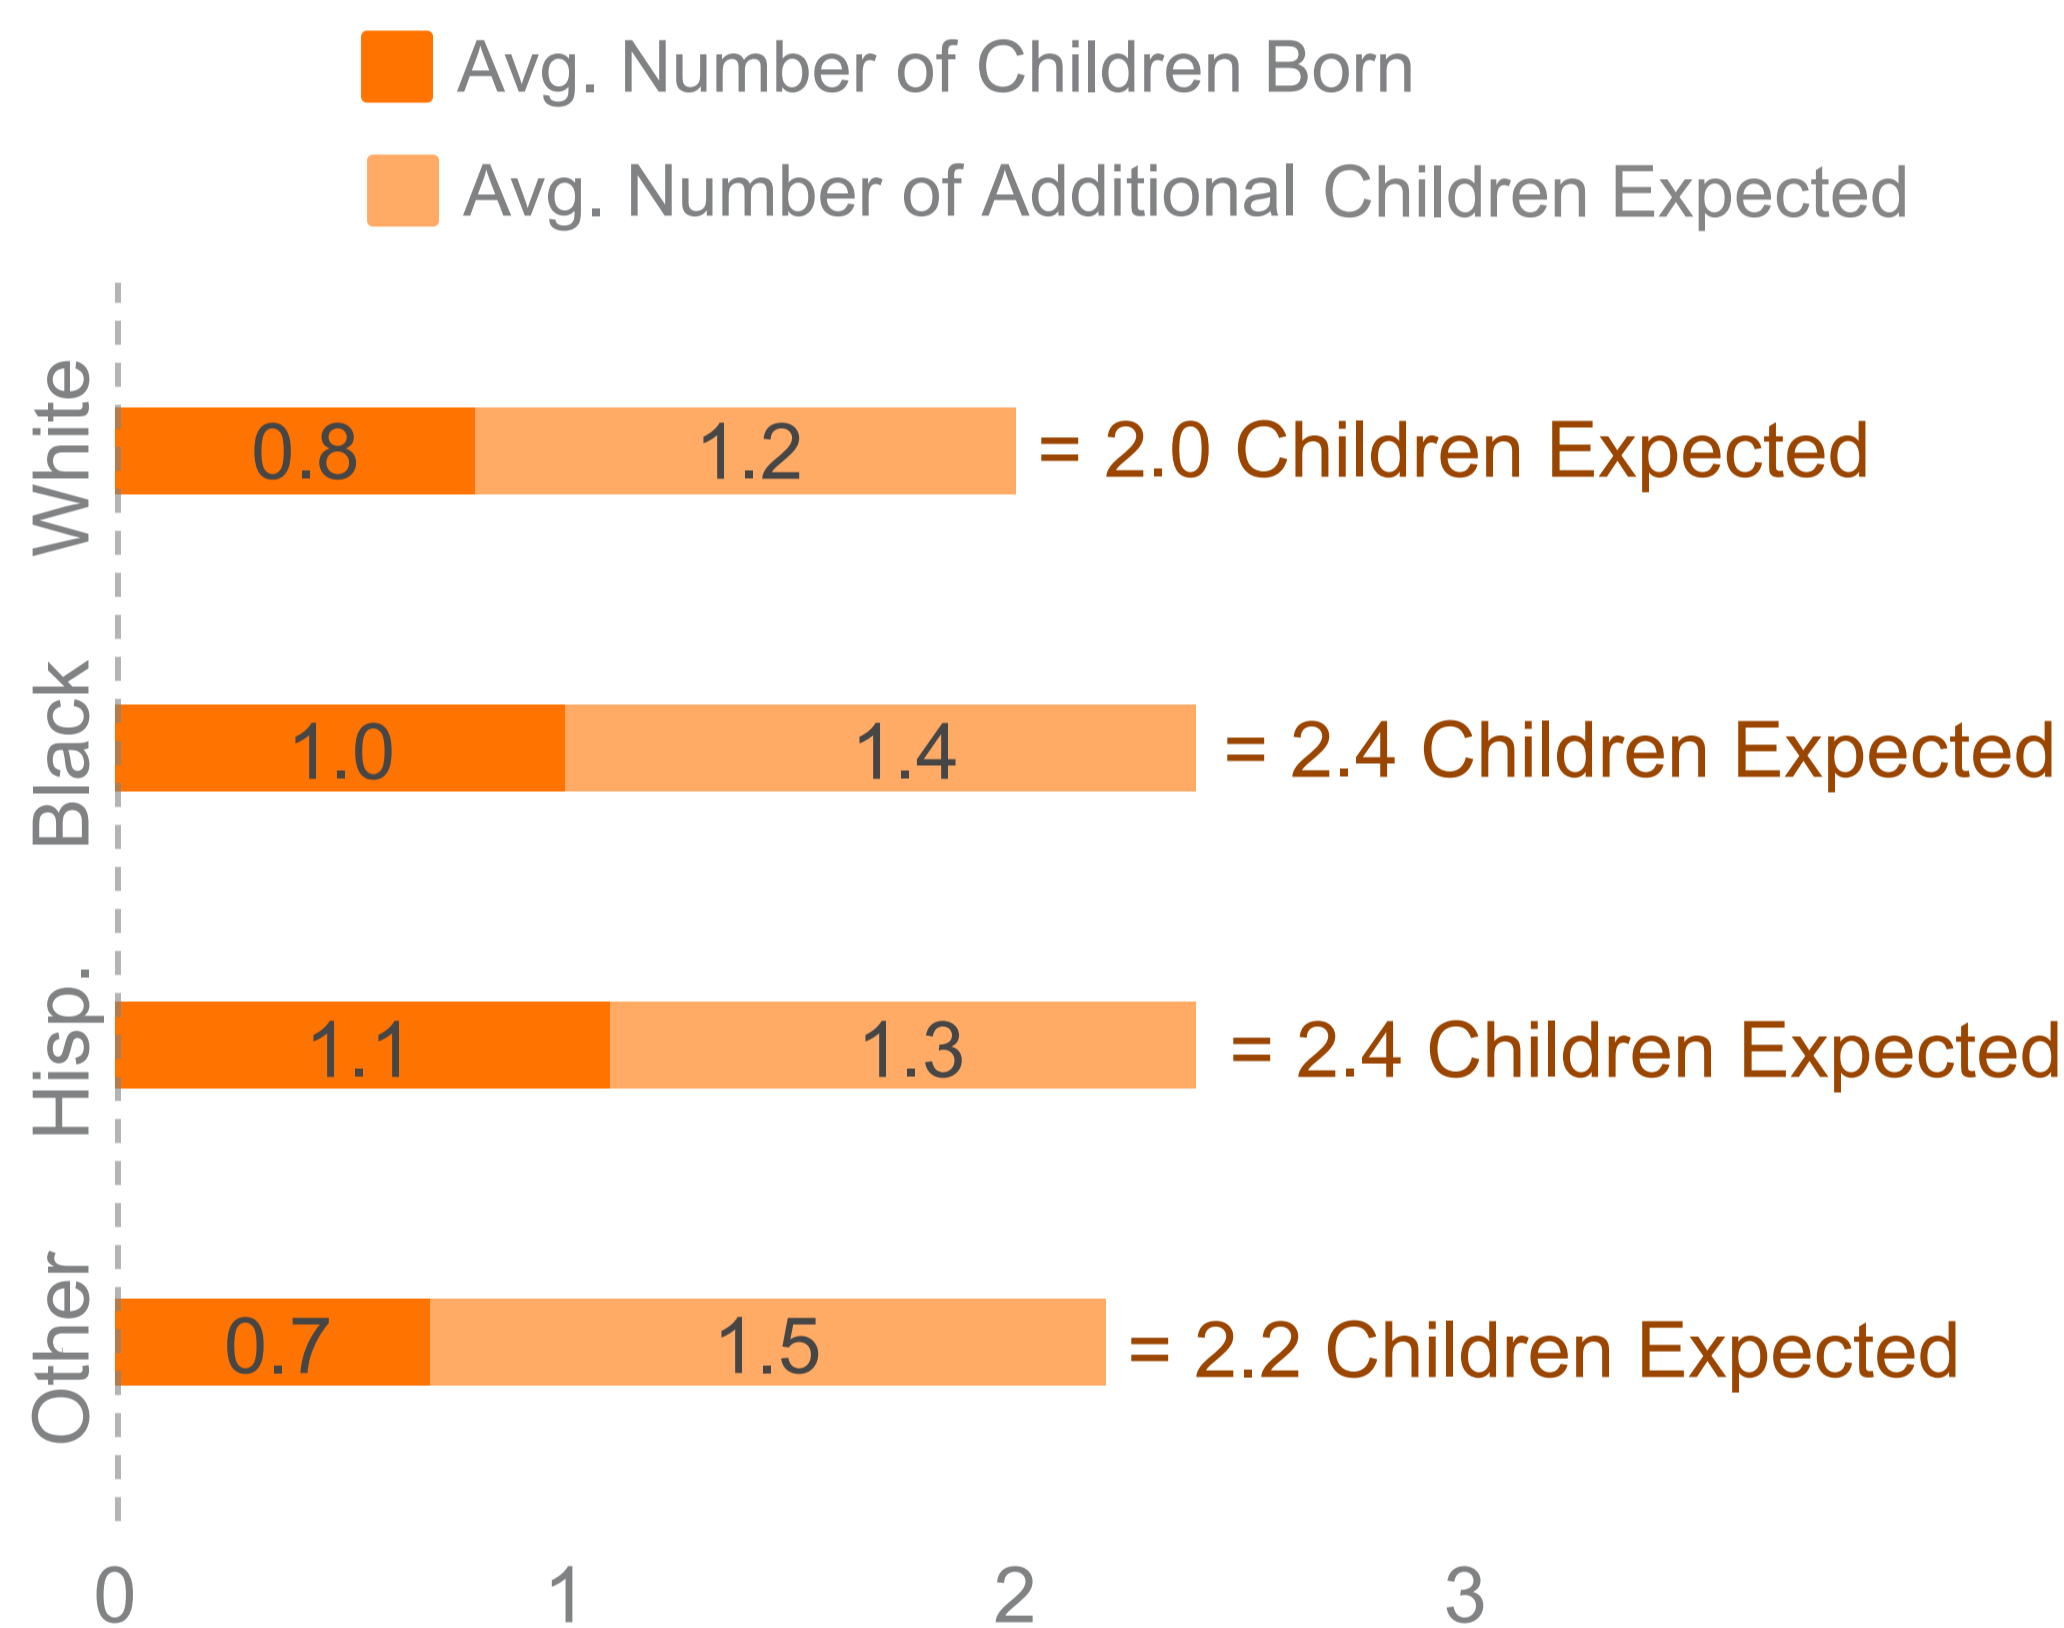

- The average number of expected children in total increased as the number of current children increased.
- Men with no children and men with one child expected to have a total of just under two children on average, at 1.8 and 1.9, respectively.
- The average number of total expected children for men with three or more children was 3.7, which differs from the overall average (2.2) by 1.5 children, and was the largest variation observed.

Variation in Total Number of Expected Children, by Demographic Characteristics

There was little variation in the total number of expected children by age or education (not shown). However, there was some variation by race and ethnicity.

- At 2.0 total expected births, White men had the lowest expected children of any race or ethnic group.
- Both Black and Hispanic men expected to have an average of 2.4 children, with similar numbers of children already born and additional children expected.
- Men in the “Other” category had the fewest current number of biological children and the highest number of additional children expected, with a total expected of 2.2 children.

Timing of Expected Childbearing

As men grow older, those who have not yet reached their desired number of children shortened their childbearing timeline.

- Among men in the youngest age group who expected to have a child in the future, only 5% intended to have a child in the next two years and 25% within a two to five-year timeframe.
- Among men aged 25-34 who expected a child in the future, nearly 60% intended to have a child within the next two to five years.
- Nearly half (45%) of older men (35-44) who expected to have a child in the future intended to do so within two years, and a nearly equal percentage (46%) expected to do so in two to five years.
